Title : Processing milk by Engineer Meleshin's method

Periodical : Nauka i zhizn' 21/7, 16 and insert page, July 1954

Abstract : A description is given of a new method of processing milk through the cream-separating stage, pasteurization, and butter making in 30 minutes. The illustration shows the old method which produces 400 kg. of butter in six hours and the new method which produces the same amount in one hour. Illustrations.

TITLE: Stability of the Q-factor in an inductive circuit with p-n junctions

SOURCE: IVUZ. Radiotekhnika, v. 7, no. 3, 1964, 316-321

TOPIC TAGS: p n p transistor, reactive transistor, inductive transistor, Q factor stability, collector voltage effect, collector voltage stability, Q factor measuring bridge

ABSTRACT: The relationship between the Q-factor stability of inductive and reactive transistors and voltage under conditions of collision ionization in a collector junction was investigated. The cause of the Q instability was analyzed. It was shown that with the introduction of a loss-compensating negative resistance into the circuit, the Q-factor stability sharply decreases. Therefore, a large increase in Q is undesirable. The inductance of the discussed circuit depends only slightly on the collector voltage. If a considerable improvement of

Card 1/2

ACCESSION NR: AP4042848

the Q-factor is necessary special measures for supply voltage regulation must be taken. The Q-factor variation in an inductive transistor circuit as a function of collector voltage was investigated experimentally. A bridge with an oscillograph indicator was used. This permitted the measurement of the inductive Q-factor from 0.1 to 10 within the frequency range of 1 kc to 5 Mc, and with a 20 per cent accuracy at 50 mv. TITLE: Effect of the film resistance on the frequency characteristics of film capacitors

SOURCE: Radiotekhnika, v. 20, no. 11, 1965, 69-74

TOPIC TAGS: microelectronic thin film, thin film capacitor

ABSTRACT: The effect of metal-film loss on the parameters of a 3-thin-film capacitor is theoretically analyzed, and practical formulas for designing such capacitors and circuits containing them are developed. Regarding the capacitor as a series RC-circuit, formulas for the loss resistance, Q-factor, and impedance for higher and lower frequencies are derived. Frequencies at which the current-voltage phase shift reaches 45° are considered; the impedance is largely determined by the film width and is independent of the film length. The frequency band that corresponds to $\leq 10\%$ error of the formulas is indicated. Orig. art. has: 3 figures and 32 formulas.

TITLE: Calculation of film two-terminal networks with distributed parameters

SOURCE: Radiotekhnika, v. 21, no. 2, 1966, 55-69

TOPIC TAGS: thin film circuit, circuit microminiaturization ²⁵

ABSTRACT: A thin-film distributed-RC-structure (see figure) is theoretically considered. Dielectric backing 1 is coated with resistive film 2, dielectric film 3 and resistive film 4; metal films 5 are intended for connecting external circuits. This structure is replaced with an equivalent diagram consisting of two resistors and one capacitor. Various connections of these elements yield ten different two-terminal networks. Formulas for $\text{Re}\{Z\}$, $\text{Im}\{Z\}$, $\text{tg } \varphi$, and $|Y|$ for all networks are tabulated as are formulas for the equivalent parameters R_p , C_e , and $\text{tg } \varphi$ (for numerical calculations). AUTHORS: Prozorovskiy, V. Ye.; Kolesov, L. N.; Sementsov, V. I.; Afanas'yev, K. L.

TITLE: Analysis of some parameters of inductive and reactive transistors

SOURCE: IVUZ. Radiotekhnika, v. 6, no. 6, 1963, 616-622

TOPIC TAGS: inductive transistor, reactive transistor, microelectronics, solid state microelectronics, inductive transistor inductance, inductive transistor Q, reactive transistor inductance, reactive transistor Q

ABSTRACT: The inductance and Q factor of transistors with large base-circuit resistance (inductive transistor) and of transistors with a phase-shifting network connected in parallel to the base resistance (reactive transistors) are determined analytically by using the transistor equivalent circuit. It is shown that a decrease in the thickness of the base of an inductive transistor to a value $\approx 20\text{--}30\mu$ ($f_{\alpha} \approx 2\text{--}4$ Mc) increases the value of Q, but beyond that

Card 1/2

ACCESSION NR: AP4012356

the Q decreases. The maximum Q obtainable by using an inductive or reactive transistor as an inductance is $0.5(1 - \alpha)^{-1/2}$. The frequency at which the maximum Q is reached is $f_{\alpha}(1 - \alpha)^{1/2}$ and $(1 - \alpha)^{1/2}/2\pi r_e C$ for the inductive and reactive transistors, respectively, where $r_e C$ is the emitter time constant. The reactive transistor is superior to the inductive one in that the dependence of its Q on the inductance is less pronounced, so that higher Q can be obtained with large inductances at low frequencies. Orig. art. has: 6 figures and 29 formulas.

TITLE: Concerning the technology of producing some ferromagnetic films and indirectly investigating their properties

SOURCE: IVUZ. Radiotekhnika, v. 6, no. 6, 1963, 611-615

TOPIC TAGS: microelectronics, microsystem electronics, thin film circuit, ferromagnetic film, film production, permeability, magnetic material, thin film

ABSTRACT: For the purpose of obtaining ferromagnetic films with maximum permeability and maximum resistivity (so as to reduce the eddy currents), the authors investigate the properties of film evaporated in vacuum from sintered ferrite (8.89% Fe_2O_3 , 29% NiO, 2.54% CuO, and 0.98% CaCO_3). Best results were obtained by evaporating the film from a crucible rather than directly from a tungsten or molybdenum evaporator. The evaporator temperature reached 1600C.

Card 1A 2

ACCESSION NR: AP4012355

the evaporation rate from the crucible was 3--15 g/sec, and the film deposition rate was 500--3000 Å/sec. Factors governing the stability and properties of the film are discussed. It is concluded that films so evaporated have a higher resistivity than metallic films and are therefore preferable. Orig. art. has: 5 figures and 1 table.

TITLE: Losses in thin-film capacitors with silicon monoxide as the dielectric

SOURCE: IVUZ. Radiotekhnika, v. 9, no. 4, 1966, 503-509

TOPIC TAGS: electric capacitor, thin film circuit, *dielectric material*

ABSTRACT: Formulas are derived for calculating the loss tangent of thin-film capacitors with rectangular aluminum plates and with silicon monoxide as the dielectric.

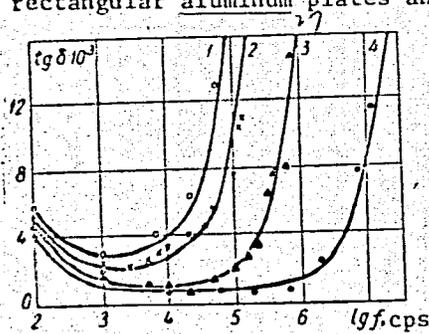

Fig. 1. Loss tangent as a function of frequency

1 - Dielectric film thickness, 0.03 μ ;
2 - 0.06 μ ; 3 - 0.29 μ ; 4 - 5.6 μ .

L 02987-57

ACC NR: AP6033218

It was assumed that the relaxation losses in the dielectric, the permeability of the dielectric, and the surface resistivity of the plates are known. To check the results of the theoretical analysis, several capacitors were built and tested. Dielectric films were obtained by evaporating a compressed mixture of one part silicon and two parts silicon dioxide. The dielectric films thus obtained were highly stable and losses in them varied only slightly with thickness. The frequency dependence of the

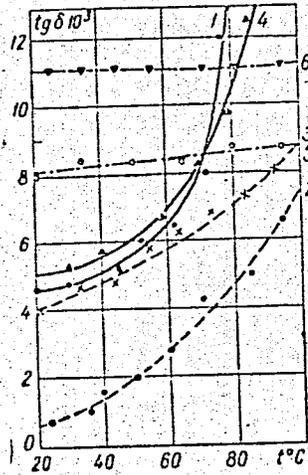

Fig. 2. Loss tangent as a function of temperature

L 02987-67

ACC NR: AP6033218

loss tangent in capacitors with dielectrics of different thickness is illustrated in Fig. 1; its temperature dependence is shown in Fig. 2. Temperature characteristics are given for two capacitors with dielectric films 2.3 μ and 0.03 μ thick, respectively. Generally, it was noted that capacitance was affected only slightly by frequency, temperature, and variation in voltage. Orig. art. has: 19 formulas and 7 figures. C

TITLE: Calculation of the thermodynamic functions of diatomic gases
at elevated temperatures by direct summation on an electro-
nic machine

PERIODICAL: Referativnyy zhurnal, Khimiya, no. 24, 1961, 62, abstract
24B422 (Tr. In-ta goryuchikh iskopayemykh AN SSSR, v. 12
1961 196 - 205)

TEXT: A very rapid and precise method is proposed for the calculation
of the thermodynamic function tables of diatomic perfect gases at tempera-
tures of up to 20,000 to 25,000°K. The statistical sums are calculated,
for the rotational vibrational and electron states of the molecule in
question, by direct summation through the really existant energy levels,
using a high-speed electronic computer. For this kind of calculation the
molecular constant which most precisely describes all the energy levels of

Card 1/3

Calculation of the thermodynamic ...

32326
S/081/61/000/024/008/086
B138/B102

the molecule must be known, as also the highest values of the quantum numbers up to which summation is to be made. A method is described for calculating vibrational constants and maximum vibrational quantum numbers $v(\max)$ using the conditions for the convergence of the vibrational levels toward the dissociation limit. A method has been developed for calculating values of rotational quantum numbers $J(\max)$ for each vibrational state, using the properties of the effective potential curves of the rotating molecule. As an example some results are given of the calculation of the main state $x^3\Sigma_g^-$ of an O_2 molecule. In particular, to describe the energy of vibrational levels (in cm^{-1}) the equation $G_0(v) = 1568.077 v - 11.706 v^2 - 0.00255 v^3 - 0.00224 v^4 - 0.0000821 v^5$ is derived, which converges towards the 41261 cm^{-1} limit at $v(\max) = 42$ (experimental values of dissociation energy of O_2 are $41260 \pm 15 \text{ cm}^{-1}$). $J(\max)$ values are found for all v . The thermodynamic functions of molecular oxygen are given for the following temperatures: 5000°K (63.395 and 73.038) 10000°K (70.457 and 79.942).

PURPOSE: This reference book may be used in scientific-research and experimental-design work in institutes, design offices, and schools of higher education, as well as for training specialists in chemical thermodynamics and thermal physics.

COVERAGE: Volume 1 of this work deals with methods for calculating thermodynamic properties and with the selection of constants required for the calculations. Volume 2 contains tables of thermodynamic properties (reduced thermodynamic potential, entropy, enthalpy, and the logarithm of the dissociation or ionization constants of equilibrium) compiled where data were lacking, on the basis of published and unpublished material from a number of Soviet research institutes. Thermodynamic properties for the ideal gas

state are presented in table form for 335 gases, 44 liquids, and 45 solids compounded from 33 chemical elements and their isotopes, viz.: H, D, T, He, Li, Be, B, C, N, O, F, Ne, Na, Mg, Al, Si, P, S, Cl, Ar, K, Ca, Br, Kr, Re, Sr, Zr, I, Xe, Cs, Ba, Hg, and Pb. Thermodynamic properties are given for the following 22 gases in the range from room temperature to 20,000°K: H, H⁺, H⁻, O, O⁺, H₂, O₂, O₃, OH, OH⁺, H₂O, N, N⁺, Na, N₂, NO, NO⁺, C, C⁺, CO, CO⁺, and e⁻; for the 14 least stable gases up to 4000°K; and for the remaining 299 gases up to 6000°K. Virial coefficients for 34 gases are also given up to 6000°K.

po khimii. Institut prikladnoy khimii.

Resp. Ed.: V. P. Glushko, Academician, L. V. Gurvich, G. A. Knachkuruzov, I. V. Veyts, and V. A. Medvedev; Ed. of Publishing House: K. P. Gurov; Tech. Ed.: V. G. Laut.

PURPOSE: This reference book may be used in scientific-research and experimental-design work in institutes, design offices, and schools of higher education, as well as for training specialists in chemical thermodynamics and thermal physics.

COVERAGE: Volume 1 of this work deals with methods for calculating thermodynamic properties and with the selection of constants required for the calculations. Volume 2 contains tables of thermodynamic properties (reduced thermodynamic potential, entropy, enthalpy, and the logarithm of the dissociation or ionization constants of equilibrium) compiled, where data were lacking, on the basis of published and unpublished material from a number of Soviet research institutes. Thermodynamic properties for the ideal gas

Card 2/2

Thermodynamic Properties (Cont.)

state are presented in table form for 335 gases, 44 liquids, and 45 solids compounded from 33 chemical elements and their isotopes, viz.: H, D, T, He, Li, Be, B, C, N, O, F, Ne, Na, Mg, Al, Si, P, S, Cl, Ar, K, Ca, Br, Kr, Re, Sr, Zr, I, Xe, Cs, Ba, Hg, and Pb. Thermodynamic properties are given for the following 22 gases in the range from room temperature to 20,000°K: H, H⁺, H⁻, O, O⁺, H₂, O₂, O₃, OH, OH⁺, H₂O, N, N⁺, N₂, NO, NO⁺, C, C⁺, CO, CO⁺, and e⁻; for the 14 least stable gases up to 4000°K; and for the remaining 299 gases up to 6000°K. Virial coefficients for 34 gases are also given up to 6000°K.

TITLE: Problems of the arc welding of boron-treated austenitic chromium-nickel alloys

SOURCE: Avtomaticheskaya svarka, no. 1, 1966, 1-5

TOPIC TAGS: arc welding, boron, austenite steel, chromium base alloy, nickel base alloy, crack propagation, oxidation

ABSTRACT: Argon arc welding, automatic submerged arc welding and manual welding of steels containing various proportions of B (0.005-2.0%) was carried out to determine the effect of B on the structure of the metal of Cr-Ni welded joints. The probability of the oxidation of various elements is determined by their affinity toward oxygen and, in this connection, submerged arc welding based on the use of the flux 48-OF-6 (varying content of SiO₂), with wire electrodes containing various concentrations of B and Ti, established that the affinity of B toward oxygen is greater than that of Si, smaller than that of Al and roughly equal to that of Ti (Fig. 1). During welding with electrodes coated with a relatively oxidation-resistant layer of calcium fluoride which is usually employed in the welding of Cr-Ni austenitic steels, the burnout

(oxidation) of B in the electrode rod is ~0.7%. Thus, B is an extremely active element with respect to oxygen, and even small amounts of oxidizing agents (e.g. oxides of elements with smaller affinity toward oxygen) may lead to considerable losses of B during welding. The burnout of B from metal may be reduced in two ways: by using more energetic deoxidizing agents than B (e.g. Al) or by treating the slag with boron oxides. Treatment with B of Cr-Ni steels in the austenitic class as well as of welded joints of an analogous composition leads to the appearance of Cr-rich borides in the structure. This contributes to a change in the ratio between the ferrite- and austenite-forming elements in the solid solution. Accordingly the authors propose formulas for taking into account the corresponding changes in the composition and volume of the solid solution and in the equivalent values of Cr and Ni. When the metal of purely austenitic welded joints contains minute amounts of B (0.01-0.35% B), it is extremely prone to form hot cracks. On the other hand, if it contains 0.35-1.5% B, it is sufficiently resistant to hot cracking. Orig. art. has: 4 figures, 3 formulas, 2 tables.

AUTHOR: Prozorovskiy, Yu. 107-58-3-24/41

TITLE: Wide-Band Amplifier (Shirokopolosnyye usiliteli)

PERIODICAL: Radio, 1958, Nr 3, pp 34 - 35 (USSR)

ABSTRACT: A number of correction systems has been developed for RC amplifier stages which reduce the parasite capacitance and widen the pass band of the stage several times while maintaining the original amplification factor. The application of simple, so-called two-band correction systems, as shown by Figure 1, will widen the pass band by approximately two times as compared to uncorrected amplifier systems. The pass band may be widened three to four times by more complicated four-band correction systems. However, an unlimited widening of the pass band cannot be achieved in this way, since the amplification factor of one stage may become less than one at very low plate loads, whereby the amplifier will weaken the signals instead of intensifying them, regardless to the number of stages it may contain. The formula listed below can be used to determine the widest frequency pass band f , which may be achieved by a multi-stage RC amplifier (with given amplification factor K)

Card 1/3

Wide-Band Amplifier

107-58-3-24/41

$$f_{\text{cycles}} = \frac{0.075a\beta}{\sqrt{lgK}}$$

where β designates the correction factor, characterizing the correction system applied in the amplifier, and a is the "quality factor" of the tube which is equal to the ratio of its characteristic steepness to the total amount of capacities connected parallel to the anode load (capacitance of tubes, wiring, tube sockets, etc in regard to ground). The formula shows that with given K , a wide pass band may be obtained when selecting effective correction circuits or using tubes with high quality factors. Modern HF pentodes permit to build RC amplifiers with a pass band ranging from sound frequency to 100 - 150 megacycles with adequate amplification. Figure 2 shows the frequency characteristics of two models of such amplifiers, their circuit diagrams are shown in Figure 3. Both amplifiers have pass bands ranging in sound frequencies to 100 megacycles with an amplification of 35 - 38 db (60 - 80 times). The first amplifier has six stages. The second

Card 2/3

Wide-Band Amplifier

107-58-3-24/41

amplifier has seven stages and is built on a similar principle as the first, but has an additional resistance in the control grid circuits of the tubes. In both systems, tubes of type "6Zh9P" are used, having a characteristic of the magnitude 15 - 18 milliamps/volt and rather small parasite capacitances. Analogous amplifiers may be built with "6Zh1P" tubes. There is one diagram, one circuit diagram and one graph.

SOV-109-3-4-8/28

AUTHOR: Prozorovskiy, Yu. N.

TITLE: A Method of Analysis of the Amplifiers with Distributed Parameters (Metod analiza usiliteley s raspredeleennymi postoyannymi)

PERIODICAL: Radiotekhnika i Elektronika, 1958, Vol 3, Nr 4, pp 518-521 (USSR)

ABSTRACT: The distributed amplifiers with grounded-cathode stages have been analysed and investigated by a number of authors (Refs.1 and 2). It is pointed out that it is also possible to design the distributed amplifiers with grounded-anode or grounded-grid stages. All the three types of the distributed amplifier can be analysed by the method proposed by Prozorovskiy (Ref.2), in which it is assumed that the analysed system consists of a finite number of quadripoles. It is assumed, for the purpose of analysis, that an amplifying stage can be represented by a generalised multipole shown in Fig.2. The multipole is divided into 3 component multipoles such that the system II represents the amplifying

Card 1/3

A Method of Analysis of the Amplifiers with Distributed Parameters

tube and the sections I and III are two identical passive multipoles whose matrix is expressed by Eq.(1); R_{oa} and R_{oc} are ohmic resistances of the coils of the line, and F_a , F_c are the coefficients characterising the losses in the lines as a function of frequency. The matrix of the amplifying tube quadripole can be written as Eq.(2), in which the elements a , b , c and d are expressed by Eq.(3). From the above, the operation of a single amplifying stage can be described by Eq.(4). Matrices of the tube quadripoles for the 3 above-mentioned cases can be written as Eqs.(7), (8) and (9) respectively; symbols Y_{BX} and Y_{BbIX} denote the input and output admittances of the tubes and S represents the mutual conductance of the tubes. From the above it is shown that an amplifying section of the grounded-anode type (see Fig.3b) can be described by Eq.(12); an analogous expression for a grounded

PERIODICAL: Radio, 1957, # 8, pp 27-28 (USSR)

ABSTRACT: The 12th All-Union competition of DOSAAF short wave amateurs in radio communication and receiving was recently finished. In the first round it was required to contact the greatest number of different stations. In the second round it was necessary to contact the greatest number of provinces and to contact all the Union republics in the shortest time possible. Each participant also tried to make the greatest number of contacts within one hour. The STALINO radio station UB5KAB became the All-Union champion of the collective stations, the call numbers UA4KCE (SARATOV) and UA3KWA (KALUGA) were second and third respectively.

(O vybore vedeousiliteley, Russian).
PERIODICAL: Radiotekhnika, 1957, Vol 12, Nr 3, pp 57 - 61 (U.S.S.R.)
Received: 5 / 1957 Reviewed: 6 / 1957
ABSTRACT: Those domains are investigated where it is purposeful to use a multicascade amplifier of one or the other type (with sufficiently great amplifying coefficient). These investigations are carried out by means of approximated formulae, without consideration of scatterings in transition characteristics. It is assumed that the amplifiers to be compared are equivalent, in case that amplifying coefficients and front duration of the transition characteristics of both amplifiers are equal. The minimum front duration of the transition characteristics of a corrected RC amplifier is investigated and the corresponding formula is derived. If the minimum front duration τ_{KV} of the corrected amplifier is determined, the most favorable cascade number can be determined herefrom. It is purposeful to use corrected RC amplifier where the given front duration of the transition characteristics is larger than the minimum front duration, obtained by such amplifiers. If $\tau_{given} < \tau_{KV_{min}}$, amplifiers with distributed constants should be used. The most favorable number of tubes in the amplifiers with distributed constants is investigated

TITLE: Fast-acting electronic instruments transforming continuous into sampled data and vice versa, for wide band communication transmitting systems with pulse code modulation

PERIODICAL: Referativnyy zhurnal. Avtomatika i radioelektronika, no. 3, 1961, 31, abstract 3 G212 (V sb. Teoriya i primeneniye diskretn. avtomat. sistem, M., AN SSSR, 1960, 329-338)

TEXT: The pulse systems for transmitting information which possess better interference killing features are now beginning to be used increasingly. The signals transmitted by such a system are undergoing double transformation: they are coded into a sequence of pulses before being applied to the line and at the other end of it

are decoded and their original shape reinstated. Considerable advantages are shown by transmitting systems using pulse code modulation (MKM (IKM)) which hardly increase the noise during retransmission. The principle of pulse code modulation is that the "quantized" discrete values of the continuous signal are transmitted by means of a binary pulse code which reproduces different combinations of the same pulses and intervals. The number of signals sent during every code group remains constant and their combination depends on the adopted law of coding. Usually the Sears CRT is used in pulse code modulation (Sears, R.W., Bell system Techn. J. 1948, 27, No. 1, 44-47). This tube has certain disadvantages which limit the range of its application to low frequencies only. A fast acting coding CRT with internal delay is described. The tube may be used in systems with pulse duration $< 10-20 \mu\text{sec}$. A decoder is described which may be used in wide band systems. Certain electronic instruments are also described used for restoring the shape, amplitude and time dependence of pulses forming the code groups. Coding, decoding and restoring electron beam instruments are described for use in wide

band pulse code transmitting systems. These instruments, or their sub-assemblies, may find application in other branches of technology, such as automatic control systems, remote control etc. 5 references. [Abstracter's note: Complete translation]

TITLE: Fast Scan Generator

PERIODICAL: Pribory i tekhnika eksperimenta, 1960, No. 6,
pp. 131 - 132

TEXT: In the majority of commercial oscillographs the time base is no faster than 1-2 μ s per scan. As a rule, specially developed fast-scan generators do not work at slow speeds and consequently two separate time-bases are needed. The scanning generator shown in Fig. 1 works both at slow speeds and over very short time intervals (8-10 \cdot 10⁻⁹ secs per scan). Triodes \mathcal{N}_{1a} and the inner electrodes of \mathcal{N}_2 form a single-shot multivibrator triggered by a negative input pulse. The multivibrator square wave is terminated by the blocking oscillator \mathcal{N}_{3b} . The wave is applied to the grid of the discharge tube \mathcal{N}_4 . The scan speed may have 5 values between 10 and 0.1 μ s per scan by setting the switch Π .

Fast Scan Generator

The output stage is a pair of 6П13С (6P13S) tubes whose anodes are connected to the horizontal plates of the c.r.t. The anode supply is stabilized to avoid scan modulation. This generator will scan a 13-50-301 (13-L0-31) tube in 0.1 μ s at a rate of up to 10 kc/s. Apart from a portion at the beginning, the scan is linear. There are 1 figure and 1 Soviet reference.

TITLE: A Wide-band Amplifier for a Typical Oscillograph
(Shirokopolosnyy usilitel' dlya tipovogo ostsillografa)

PERIODICAL: Pribory i tekhnika eksperimenta, 1959, Nr 2,
pp 143-145 (USSR)

ABSTRACT: The currently available wide-band amplifier type UR-4 is intended to work at a load of 6.5 pF. A typical oscillograph, for example the 25-I, has a deflection-plate capacitance of 20-25 pF. The UR-4 amplifier cuts off between 55 and 60 mc/s with such a load. This is unsatisfactory for studies on milli-microsecond pulses. The 5-stage distributed amplifier whose circuit is in Fig 1 has a cut-off frequency of 150 mc/s and a gain of 55 db. With oscillograph type 25-I the height of the pulse on the screen may be 50 mm. The input stage is matched to 275 ohms. The second stage has compensation for the overall frequency characteristic. The third stage is a voltage amplifier. These preliminary stages use the type 6Zh9P valve. The fourth and fifth stages use the 6P15P valve to develop a sufficient power to give as large an output voltage as possible. The preliminary and final stages and the entire amplifier and

oscillograph are linked by precise lengths of RK-50 cable. Winding data are given for coils in Table 1, while Table 2 presents the anode and screen currents. The valves are biased to favour a positive pulse output so that unless a small signal is used a harmonic measurement of frequency response will encounter distortion. Fig 2 is a frequency response taken from the screen of the oscillograph using a GSS-7 signal generator as source. Curve 1 shows the effect of shunting the output terminals with a 150 ohm resistor; the corresponding behaviour with a 1 μ pulse is in Fig 3. When operating with another type of oscillograph the cable length would need to be modified.
